ABSTRACT
Knowledge Distillation (KD) is known for its ability to compress large models into low-complexity solutions while preserving high predictive performance. In Acoustic Scene Classification (ASC), this ability has recently been exploited successfully, as underlined by three of the top four systems in the low-complexity ASC task of the DCASE’21 challenge [1] relying on KD. Current KD solutions for ASC mainly use large-scale CNNs or specialist ensembles to derive superior teacher predictions. In this work, we use the Audio Spectrogram Transformer model PaSST, pre-trained on Audioset, as a teacher model. We show how the pre-trained PaSST model can be properly trained downstream on the TAU Urban Acoustic Scenes 2022 Mobile development dataset [2] and how to distill the knowledge into a low-complexity CNN student. We study the effect of using teacher ensembles, using teacher predictions on extended audio sequences, and using Audioset as an additional dataset for knowledge transfer. Additionally, we compare the effectiveness of Mixup and Freq-MixStyle to improve performance and enhance device generalization. The described system achieved rank 1 in the Low-complexity ASC Task of the DCASE’22 challenge [3].

Index Terms— Patchout Spectrogram Transformer, Mixup, Freq-MixStyle, Knowledge Distillation

1. INTRODUCTION
Acoustic Scene Classification (ASC) aims to build a model that accurately predicts a scene label given an audio recording. Convolutional Neural Networks (CNNs) are well-established models that dominate the field of ASC [10–14]. Low-complexity solutions are of increasing interest, making the ASC systems runnable on edge devices. Model compression techniques to reduce complexity include Parameter Pruning [12,15], designing efficient network architectures [10,11], and Knowledge Distillation (KD) [12–14]. KD recently showed promising results for ASC, with three out of the top four systems applying KD in the low-complexity ASC task of the DCASE’21 challenge [1].

This paper focuses on distilling knowledge from Patchout faSt Spectrogram Transformers (PaSST) [15] into low-complexity CNNs, the winning approach of the DCASE’22 low-complexity ASC task [3]. The TAU Urban Acoustic Scenes 2022 Mobile development dataset [2] and the low-complexity constraints of the DCASE’22 challenge define an ASC scenario involving various challenges:

C1 Limits on the number of parameters and the number of multiply-accumulate operations.

C2 Scenes are recorded using different recording devices, resulting in a domain shift.

C3 1-second audio snippets are provided compared to 10-second snippets in the ASC task of the DCASE’21 challenge [1]. Shorter audio files contain less information and are more challenging to classify.

The system studied in the following tackles C1 by using KD with PaSST [15] models as a teacher and a low-complexity CNN as a student. Regarding C2, the domain shift caused by different recording devices is counteracted by Freq-MixStyle [16], a modified version of MixStyle [17], operating on frequency statistics. The 1-second audio snippets described in C3 result from splitting the 10-second snippets of the TAU Urban Acoustic Scenes 2020 Mobile development dataset [2] into ten pieces. The provided segment identifiers allow for reassembling the complete 10-second files. We train all models on randomly cropped 1-second pieces from the re-assembled 10-second files to increase the diversity in the training data. Reassembling the 10-second files additionally allows for obtaining superior teacher predictions for KD, as described later.

The related work regarding the system’s building blocks is described in Section 2. Section 3 introduces student and teacher architectures and the PaSST downstream training. Section 4 describes how student and teacher are combined in a KD setup and sets the stage for the results presented in Section 5. The paper is concluded in Section 6.

2. RELATED WORK

2.1. ASC Architectures
In the past years, Convolutional Neural Networks (CNNs) became the most prominent solution to process spectrograms and dominated previous DCASE challenges [14,15]. Restricting the receptive field of CNNs, known as Receptive Field Regularization, was shown to be particularly well suited for ASC tasks [18,19].

Inspired by Vision Transformers (ViT) [20], transformers capable of processing spectrograms to solve audio tasks have been proposed recently. In this regard, Audio Spectrogram Transformers (AST) [21], pre-trained on computer vision tasks, have been adapted to the audio domain and achieved state-of-the-art results on Audioset [22]. Image [20,23] and spectrogram [15,21] transformers extract overlapping patches with a certain stride from the input image and add a positional encoding. Patchout faSt Spectrogram Transformer (PaSST) [15] disentangles frequency- and time-encodings, simplifying downstream training on shorter audio clips. PaSST additionally introduces Patchout, a mechanism that drops parts of the input sequence to improve generalization and reduce
memory and computational complexity in the quadratically scaling attention layers.

2.2. Knowledge Distillation in ASC

In KD [12][14], the aim is to compress the knowledge of a possibly large number of complex teacher models into a low-complexity student model without significant performance loss. The student minimizes a weighted sum of hard label loss and distillation loss, as shown in Eq. 1. The distillation loss matches student and teacher predictions based on the Kullback-Leibler divergence between soft targets: \( L_{DIST} = D_{KL}(p_{\text{teacher}} || p_{\text{student}}) \). By minimizing the distillation loss, the student learns to mimic the teacher.

\[
L_{TOTAL} = L_{LABEL} + \lambda L_{DIST} (1)
\]

The soft targets \( q \) are created from the logits \( z \) by computing \( q = \text{softmax}(z/T) \) with a specific temperature \( T \). Raising the temperature \( T \) creates a softer distribution and allows the student to exploit the rich similarity information between classes predicted by the teacher compared to the hard labels [12].

In the low-complexity task of the DCASE'21 challenge [1], the top two systems included KD based on a pre-trained CNN teacher network [4] and a large two-stage fusion CNN teacher model [5].

Jung et al. [24] showed that learning from soft targets in a teacher-student setup has a beneficial effect as one-hot labels do not reflect the blurred decision boundaries between different acoustic scenes. Teacher superiority is achieved by using multiple audio segments of the same scene recorded at different locations to generate teacher predictions.

Another popular idea to generate superior teacher predictions is to use ensembles of specialist models. In this regard, ensembles of device-experts [25], ensembles of models trained on different audio representations [26], and ensembles of specialist models for confusing pairs of acoustic scenes [27] have been studied and successfully applied.

2.3. Mixup and Freq-MixStyle

Mixup [28] constructs virtual training samples by linearly mixing two existing samples and their labels. In particular, the coefficients of the convex sample and label combinations are drawn randomly from a Beta distribution, its shape specified by a parameter \( \alpha \). Mixup has been shown to improve generalization on ASC tasks before [29].

MixStyle [17] is introduced to enhance domain generalization by mixing channel-wise statistics of images. However, the devices-style in spectrograms primarily resides in the frequency-wise statistics. To enhance generalization across recording devices, an adapted version of MixStyle, Freq-MixStyle, is proposed in [15]. It proceeds by normalizing each frequency band and denormalizing it with mixed frequency coefficients of two different samples. Freq-MixStyle is guided by two parameters: \( \alpha \) determines the shape of the Beta distribution used to randomly draw mixing coefficients, and \( p \) specifies the probability of whether it is applied to a batch or not.

3. MODEL SPECIFICATIONS

3.1. Student Model: Compact RFR-CNN

The student model is a Receptive Field Regularized [18][19] Convolutional Neural Network (RFR-CNN) and is based on CP-ResNet which performed well in previous editions of the DCASE ASC challenge [1][2][5][29][30]. The initial width is reduced to \( W = 32 \) channels, and a grouping of 2 is applied to the penultimate block to obtain a compact model. The max-pooling layers (indicated by \( P_f \)) are adapted to perform pooling only over the frequency dimension to account for the shorter audio clips (1-second). This allows us to downscale spectrogram dimensionality while preserving temporal information. Finally, \( C = 36 \) channels are cut from the final residual block of the network to conform to the low-complexity limitations. Table 1 summarizes the architecture of the CNN used as the student.

3.2. Teacher Model: PaSST

The main criterion for selecting teacher models is the accuracy of the predictions to reflect class similarity structures. The choice of PaSST transformer models as teachers is motivated by their high performance on downstream tasks – for instance, achieving an accuracy of 76.3% [15] on the TAU Urban Acoustic Scenes 2020 Mobile development dataset [2], and their ability to recognize fine-grained acoustic events after being pre-trained on the 527 classes of Audioset [2]. The PaSST models selected for downstream training on the TAU Urban Acoustic Scenes 2022 Mobile development dataset [2] are pre-trained on Audioset and extract patches of size 16x16 with a stride of 10. We use a structured Patchout of 6 only on the frequency dimension, which means that 6 frequency bands are dropped at random during training. This is an important counter-measure to prevent overfitting on the downstream dataset [3].

Due to the short length of the audio clips, we do not apply Patchout across the time dimension. The experimental setup is the same as provided in the system’s technical report [31].

Table 2 compares a PaSST Baseline model with Mixup and Freq-MixStyle augmentation techniques. Freq-MixStyle is only applied to the raw spectrograms. While the effect on real devices is limited, Mixup and Freq-MixStyle substantially improve over the Baseline on simulated and unseen devices. In particular, on unseen devices, Freq-MixStyle significantly outperforms Mixup, underlining its superior device generalization capabilities and leading to an overall performance gain compared to Mixup. Ensemble denotes averaged logits of five PaSST models trained with different Freq-MixStyle configurations. The most significant performance gain of
Table 2: PaSST downstream training on the TAU Urban Acoustic Scenes 2022 Mobile development dataset following the official test split: Device-wise comparison between Baseline, Mixup ($\alpha = 0.3$), Freq-MixStyle ($\alpha = 0.4$, $p = 0.4$) and an ensemble of five PaSST models trained with different Freq-MixStyle configurations. The provided accuracies (%) are averaged over three runs and the last 10 epochs of training. The devices are grouped according to real devices (Real: A, B, C), the seen, simulated devices (Sim: S1, S2, S3) and the unseen, simulated devices (Unseen: S4, S5, S6).

4. KNOWLEDGE DISTILLATION FROM PASST TO CNN

Knowledge Distillation (KD) is the concept used to transfer the knowledge of the well-performing, large PaSST transformer from Section 3.2 to the low-complexity RFR-CNN introduced in Section 4.1. PaSST derives its superiority from its size and the pre-training on Audioset. Hence, in a KD setup, PaSST implicitly passes its semantically rich understanding of acoustic scenes gained from the 527 classes of Audioset to the low-complexity student model. We limit the knowledge transfer to the logits and adapt the distillation loss weight for each temperature. We select three different temperature configurations and observed that Mixup with $\alpha = 0.3$ and $p = 0.4$ yield robust results across a variety of configurations. For Student Baseline, Mixup is still slightly superior to Mixup in terms of accuracy but Mixup leads to lower log losses. Freq-MixStyle generalizes much better to unseen devices than Mixup but weakens the performance on real devices.

5. RESULTS

A summary of the results for the RFR-CNN student model, as presented in Section 4.1, is shown in Table 2. The results are categorized into Student Baseline (no KD), KD Baseline (PaSST + Freq-MixStyle as teacher) and the three KD variations presented in Section 4. In the following, we describe the effect of Freq-MixStyle compared to Mixup, the effect of KD, and the impact of the KD variations.

5.1. Mixup vs. Freq-MixStyle

We investigated different Mixup and Freq-MixStyle configurations and observed that Mixup with $\alpha = 0.4$ and Freq-MixStyle with $\alpha = 0.3$ and $p = 0.4$ yield robust results across a variety of configurations. For Student Baseline, Mixup outperforms Mixup significantly, achieving the highest performance gains on the unseen device category. In combination with KD, Freq-MixStyle is still slightly superior to Mixup in terms of accuracy but Mixup leads to lower log losses. Freq-MixStyle generalizes much better to unseen devices than Mixup but weakens the performance on real devices.

5.2. Effectiveness of KD

We experiment with three different temperature configurations and adapt the distillation loss weight $\lambda$ for each temperature. We select the best of the three settings High (H) ($T=8$, $\lambda=800$), Medium (M) ($T=3$, $\lambda=100$) and Low (L) ($T=1$, $\lambda=50$) to be listed in each row of Table 3. KD with Mixup requires high temperatures, while Freq-MixStyle tends to favour low temperature settings.
KD Baseline outperforms Student Baseline, leading to an overall accuracy improvement of 2.66% when comparing the Freq-MixStyle configurations. While the accuracy on real devices improves only slightly, the accuracy on unseen devices increases by 5.14%.

### 5.3. Effectiveness of KD variations

Using the PaSST ensemble from Table 2 as the teacher improves the results slightly but consistently for both Freq-MixStyle and Mixup, in terms of overall accuracies and log losses. However, the performance gain of more than 1 percentage point in terms of overall accuracy that the ensemble gives compared to a single PaSST model cannot be transferred to the student.

We investigate a range of values for each temperature setting for the superior teacher variation. The superior teacher predictions on the 10-second snippets are computed offline. In case of Mixup, the superior predictions are mixed accordingly and no Freq-MixStyle is applied to infer the predictions. *KD Superior Teacher* performs similarly to *KD Ensemble* using for the Mixup configuration and for the Freq-MixStyle configuration.

With *KD Audioset*, Freq-MixStyle is applied to samples from both datasets, while Mixup is not applied to the samples from Audioset since no hard labels are available. The Mixup configuration shows the best results in terms of accuracy across all Mixup settings, while the Freq-MixStyle configuration only leads to a minor accuracy improvement over *KD Baseline*. However, the Freq-MixStyle configuration achieves the lowest log loss across all Freq-MixStyle experiments. Combining Audioset with *KD Ensemble* and using Mixup leads to the highest overall accuracy and the lowest log loss.

As a final investigation, Figure 1 compares the impact of Freq-MixStyle, Mixup and the KD variations on the overall and the unseen device accuracies. The dominating factor for enhanced generalization to unseen devices is *Freq-MixStyle*, which clearly outperforms Mixup. The KD variations slightly improve over the KD baseline in terms of overall accuracy but have no significant impact on unseen device performance.

### 6. CONCLUSION

In this paper, we distilled the knowledge of a PaSST transformer model into a low-complexity CNN. We showed how the pre-trained PaSST model can be effectively adapted to a downstream task. CNN students that are taught by PaSST models perform significantly better than CNNs learning only from the hard class labels. Based on this, we experiment with three KD variations, including a PaSST teacher ensemble, a superior teacher and KD on Audioset, that show promising performance compared to the KD baseline. To enhance generalization to unseen devices, we compared Mixup with Freq-MixStyle and observed that Freq-MixStyle leads to high accuracy improvements on unseen devices for both PaSST teacher and CNN student models.
